not assessed

C

Detectability in the reference

D

Supported by the present data

- Relative expression of each candidate across the ten annotated cell types of an adult mouse spinal cord reference
- Dominant cell type and detection rate per candidate
- 16 of 29 candidates are assessable; complement and microglial activation genes are microglia-dominant

evidence
boundary

Not addressed by the present data

- The reference contains no neuronal cluster, so neuronal expression cannot be assessed for any candidate
- Single-cell expression is not spatial information
- No glial response to stimulation was measured (the stimulation dataset contains motoneurons only)
